

**AMENDMENTS TO THE SPECIFICATION**

Please replace the paragraph at page 5, lines 17-24, with the following paragraph:

To form the catalytic composition, all of the particulate components must initially be ground to at least about 3000 Blaine ~~or finer~~. Blaine is a measurement of ~~grain fineness consisting~~ of the ratio of a particle's surface area (in square centimeters) to weight (in grams). Then, these particles are blended with about one to five, preferably two to three times their weight water. An essential first reaction occurs when the solid particles are added to the water. This reaction forms reactive colloidal particles based on the connected surfaces of clays, metal oxides, zeolitic entities, and molecular sieves. The mixture is blended until the particles are completely suspended in the water.
